equation can be expressed as a linear combination of a fundamental set of solutions  $y_1, \ldots, y_n$ , it follows that any solution of Eq. (2) can be written as

$$y = c_1 y_1(t) + c_2 y_2(t) + \dots + c_n y_n(t) + Y(t),$$
 (9)

where Y is some particular solution of the nonhomogeneous equation (2). The linear combination (9) is called the general solution of the nonhomogeneous equation (2).

Thus the primary problem is to determine a fundamental set of solutions  $y_1, \ldots, y_n$ of the homogeneous equation (4). If the coefficients are constants, this is a fairly simple problem; it is discussed in the next section. If the coefficients are not constants, it is usually necessary to use numerical methods such as those in Chapter 8 or series methods similar to those in Chapter 5. These tend to become more cumbersome as the order of the equation increases.

The method of reduction of order (Section 3.5) also applies to nth order linear equations. If  $y_1$  is one solution of Eq. (4), then the substitution  $y = v(t)y_1(t)$  leads to a linear differential equation of order n-1 for v' (see Problem 26 for the case when n=3). However, if n>3, the reduced equation is itself at least of second order, and only rarely will it be significantly simpler than the original equation. Thus, in practice, reduction of order is seldom useful for equations of higher than second order.
